USING GIS FOR OIL AND GAS APPLICATIONS

Carol Wilson, Physical Scientist
Bureau of Land Management, Service Center

INTRODUCTION

This manual has been prepared to aid field personnel in using the Bureau of Land Management's (BLM) Geographic Information System (GIS) to store, retrieve, analyze and model spatial data for use in oil and gas analyses.

GIS can be used to import data files, generate contour maps and overlay several maps to create a composite map. GIS can also be used to edit data files and generate reports.

The two GIS software packages discussed in this manual include the Map Overlay Statistical System (MOSS) and the Map Analysis and Processing System (MAPS).

If you have any GIS-questions, contact the HOTLINE at (303) 236-0990.

CREATING A WELL-LOCATION MAP

You can use GIS to process non-map data and transform the data into a positionally correct, coordinate referenced map. To create a well-location map, you can use one of the following four methods:

Method 1: DIGITIZING

You can generate a well-location map by digitizing points from a basemap using an electronic graphics tablet and a manually-operated cursor that encodes the coordinates of each point using the Automated Digitizing System (ADS). You can then use ADS2MOSS to reformat the digitized map into MOSS. (Scan digitizing may be economical in the near future.)

Method 2: XYSUBJECT

If the data are from some other data base, download the ASCII (alphanumeric text) file that contains the well identifiers and the map coordinates into your working directory. Then use the MOSS UTILITY-XYSUBJECT command (menu option #16) to reformat the

coordinate data file into a file that is in a format that MOSS can read. You can then import this file into MOSS and generate a map using the IMPORT command.

Method 3: PITOMOSS

If the data is Petroleum Information (PI) data, use the PITOMOSS program. This program will create import files and multiple attribute files.

Method 4: GGWL

Another program with ADS, called Generate Graphic Well Locations (GGWL), can generate UTM coordinate values from location footages (feet from section lines). The coordinates obtained in this manner have been proven to be considerably more accurate when compared with surveyed well locations.

Methods 2 (XYSUBJECT) and 3 (PITOMOSS) are addressed in the following sections of this manual.

SECTION ONE: USING METHOD 2 (XYSUBJECT) TO CREATE IMPORT FILES

| *****NOTE:** If the PITOMOSS method is being used, skip this |
| section. |
Go to SECTION TWO.

FACTS TO REMEMBER:

- + The subject and coordinates in the coordinate file may be in any columns as long as there is one row per well.
- + The coordinates may be in latitude/longitude (decimal degrees), feet or meters.
- + Latitude/longitude must be in decimal degrees.

Latitude/longitude coordinate data can be converted to decimal degrees using the formula:

decimal degrees = degrees + (minutes * 60) +
(seconds * 3600)

This is a short example of a coordinate file:

```
49003201330000  44.6789 107.7654
49003202504900  43.9999 107.5555
```

XYSUBJECT asks you if the data is point or line data. It also asks if the coordinates are in decimal degrees, meters or feet. It then displays a counter line above the first line in the coordinate file as follows:

```
12345678901234567890123456789912345678901234567890
49003201330000  44.6789 107.7654
```

The program then asks you to enter the "format statement". The format is unique to your coordinate file. The format for the above example is:

```
(T25,F8.4,T17,F7.4,T6,I5)
```

This instructs the program to:

```
tab over to column 25 for the Y-coordinate, which is a real
  number with a field length of 8 spaces and 4 spaces to the
  right of the decimal point
tab over to column 17 for the X-coordinate, which is a real
  number with a field length of 7 spaces and 4 spaces to the
  right of the decimal point
tab over to column 6 to find the well identifier, which is an
  integer and has a field length of 5 spaces
```

The format of the output file is:

```
Line 1:   I5    Item number; this is a negative integer if
           coordinates are in latitude and longitude;
           right justified
          10x   Ten blank spaces
          30A   Subject, e.g., the well identifier
           5x   Five blank spaces
          I5    Number of coordinate pairs; integer; right
           justified
```

Line 2 for coordinates other than latitude/longitude:

```
F11.2      X-coordinate
F11.2      Y-coordinate
```

Line 2 for latitude/longitude coordinates:

```
F10.5      Longitude in decimal degrees
F10.5      Latitude in decimal degrees
```

SECTION TWO: USING METHOD 3 (PITOMOSS) TO CREATE IMPORT FILES

***NOTE: If XYSUBJECT method is being used, skip to
SECTION THREE.

OBTAINING PI TAPES: You can obtain PI data on magnetic tapes under the BLM contract using a purchase order. You should state the format required by BLM, which is as follows:

9-track data, 1600 bits per inch, 80 characters per record,
4000 characters per block

You can download the data on the magnetic tapes into your working directory on the PRIME. See FIGURE 1 for an example of the PI data file. You can then convert this file into MOSS format using PITOMOSS. This PI format conversion program automatically creates import files (.IMP) and attribute files (.ATT). The .IMP files (see example in FIGURE 2) are coordinate files used with the MOSS IMPORT command to generate well location maps; the .ATT files (see examples in FIGURES 3 and 4) are multiple attribute files used in the MOSS UTILITY-ATTRIBUTE command to attach the attributes to the wells in the map. Both types of files (.IMP and .ATT) are also created for each geologic formation given in the PI data. In the case of the formation files, each file has a 3-number code and a 4-letter abbreviation for the formation. Because PRIME does not accept a file beginning with a number, it was necessary to put a '\$' at the beginning of the file. For example:

602DKOT.IMP	becomes	\$602DKOT.IMP
602DKOT.ATT	becomes	\$602DKOT.ATT

RUNNING PITOMOSS: Mount the tapes on the PRIME and download into files in your working directory.

CAUTION: The PITOMOSS program will overwrite any previously PITOMOSS-generated files. If these files are to be saved, they must be renamed.

At the PRIMOS level, enter the command 'PITOMOSS'. The program will search through all the wells in the PI data file and select only those wells within the UTM zone, county and/or latitude/longitude window that you specified. (See FIGURE 5 for a printout of the PITOMOSS command and refer to TABLE 1 for a listing of data elements that are retrieved from the PI data and stored in the .ATT files.)

The program will also generate UTM coordinate values for the location of the wells from the latitude/longitude values in the PI data. These output files are the .IMP files, which are used in the IMPORT command to generate well-location maps.

SECTION THREE: IMPORT THE .IMP FILES (FROM EITHER METHOD ABOVE)

FACTS TO REMEMBER:

- + Input file must be in MOSS import format.
- + Must enter the correct number of map subjects that are in the .IMP file to be imported. To find this number, either SLIST the .IMP file at the PRIMOS level or use the EMACS editor to find out the last sequence number in the file.
- + Must enter a scale factor: latitude/longitude files will use 100000 as a scale factor; for other projections use 100.
- + Import files generated by PITOMOSS will be in UTM coordinates.
- + Must enter the correct data type (point).
- + Other information asked for by the command is for the map header information and has no effect on the calculations.

GENERATING THE WELL-LOCATION IN MOSS: Enter MOSS and open a project. Generate the well-location map with the IMPORT command as shown in FIGURE 6. Maps for each geologic formation can also be generated using the .IMP files and the IMPORT command.

REPROJECT THE LATITUDE/LONGITUDE MAP INTO PROJECTION OF YOUR CHOICE:

If the original coordinate file was in latitude/longitude coordinates, use the PROJECTION command to reproject the imported map to another projection, such as UTM or State Plane. The coordinates for PI data are already in UTM so no reprojection is necessary unless a projection other than UTM is required, e.g., State Plane.

SECTION FOUR: CREATE A DATA FILE

***NOTE: If PITOMOSS method is being used, skip to
SECTION FIVE.

The data file contains the multiple attributes (e.g., elevation) for each well location on the map. Naming convention gives the suffix .DAT or .ATT for the file. The following are examples of multiple attribute filenames:

PI.ATT \$602DKOT.ATT

The multiple-attribute file may be considered a two-dimensional table composed of rows and columns. Rows in the table represent individual well locations or items:

Row 1 will correspond to Item 1 in the map;
Row 2 will correspond to Item 2 in the map;
Etc.

Columns are grouped into attribute fields and each attribute field must contain a single type of data. For example, Columns 1 through 4 may be the well identifier, columns 8 through 11 the formation elevation, and so forth. The length of an attribute field must be the same within each row.

Here is an example of a multiple attribute file for 3 wells:

20133	Big Horn	KB 4150	GR	4137	D&A
20250	Marathon Oil	KB 4162	GR	4151	D&A
20300	Sierra Trading	KB 4019	GR	4007	OIL

or it could look like this without the spaces between attribute fields:

20133	Big Horn	KB4150GR4137D&A
20250	Marathon Oil	KB4162GR4151D&A
20300	Sierra Trading	KB4019GR4007OIL

FACTS TO REMEMBER:

- + There may be up to 200 attributes per well.
- + Each attribute field must contain a single type of data.
- + Attribute fields for each well must be of the same length and type.

- + An attribute field must not be greater than 70 characters in length.
- + The order of the rows must exactly match the item number order of the well-location map. (If the data file is not in the proper order, use the UTILITY-ATTRIBUTE-RESEQUENCE command to reorder the multiple attribute file.)

There are three DATA TYPES:

CHARACTER - all the printable ASCII characters including numerics, symbols and spaces. Characters are left justified within an attribute field.

EXAMPLE: Marathon Oil

REAL - positive and negative real numbers as large as 1.8×10^{63} and numbers as small as 1.0×10^{-63} . The format for real numbers is determined by the format statement. For example, F7.4 means there are a total of 7 spaces with 4 numbers to the right of the decimal.

EXAMPLE: 44.9876

INTEGER - positive and negative integer numbers as large as 32,000. No decimal points allowed. An integer larger than 32,000 must be encoded as character data or have a scaling factor applied to the values. An integer is right justified within an attribute field.

EXAMPLE: 4162

SECTION FIVE: CREATE THE DEFINITION FILE

The definition file stores information about each attribute field within a data file, such as:

ATTRIBUTE (KEY) NAME [up to 10 characters with no spaces]
 DESCRIPTION of the attribute [up to 60 characters]
 DATA TYPE [integer, real or character]
 FIELD WIDTH [number of spaces for the attribute; limitations according to data type]

Naming convention gives the suffix .DEF to a definition file. Here are some examples of definition filenames:

LL.DEF IPT.DEF

The definition files for the .ATT files from PITOMOSS have already been created and are listed in APPENDIX A. These files include:

```
PI.DEF  -- defines the attributes in the PI.ATT file
IPT.DEF -- defines the attributes in the IPT.ATT file
LL.DEF  -- defines the attributes in the LL.ATT file
FORM.DEF -- defines the attributes in the FORM.ATT file
```

***** A DEFINITION FILE IS UNIQUE TO THE DATA FILE IT IS
DEFINING. *****

| ***NOTE: If PITOMOSS method is being used, skip to |
SECTION SIX.

In the XYSUBJECT method, you must create a definition file before adding the attributes to the map. The definition file can be created interactively using the UTILITY-ATTDESCRIBE command. However, before using ATTDDESCRIBE, determine the format of the attribute file.

For example, the first line in a file WELL.ATT might look like this:

20300Sierra TradingKB4019GR4007OIL

where,

Columns 1-5	Well identification; integer
Columns 6-19	Name of the company; character
Columns 20-21	Kelly Bushing (KB); character
Columns 22-25	KB elevation; integer
Columns 26-27	Ground (GR); character
Columns 28-31	Ground elevation; integer
Columns 32-34	Final status (D&A); character

Every space has been accounted for as ATTDDESCRIBE assumes there are no spaces between attribute fields. If the file has spaces between fields, edit these spaces out of the attribute file or create the definition file and then edit the definition file.

Refer to FIGURE 7 for a printout of the ATTDDESCRIBE command.

SECTION SIX: ADDING THE ATTRIBUTES TO THE MOSS MAPS

FIGURE 8 is an example of the UTILITY-ADD ATTRIBUTES command, which adds the attributes to the well-location map by using the definition file (.DEF) and the data file (.ATT). This command creates a binary file that has a mapname.AT filename. For the PITOMOSS definition files, you must use the pathname to the directory in which the PITOMOSS definition files are stored. For example:

```
IS>MOSS>PI.DEF
```

If you create a definition file with the UTILITY - ATTDSCRIBE command, you do not need a pathname if the file is in your working directory.

SECTION SEVEN: EDITING/UPDATING ATTRIBUTES

Attributes can be edited within the UTILITY-ATTRIBUTES command (Option 3-update an existing attribute) or the EDITATT command. The first command will use a data file to modify all the values for an existing attribute; the second command allow you to use cross-hairs to locate a specific well and modify, by key entry, a specific attribute or all the attributes for that point.

SECTION EIGHT: MOSS/MAPS ANALYSES

Now you can use the following commands:

DESCRIBE mapname ATTRIBUTE to view the attribute file.
SELECT, WINDOW and PLOT the well-location map.
LEGEND mapid LABEL to plot the subject or an attribute next to the well locations.
SELECT mapname ATTRIBUTE to select a specific attribute for plotting on the screen.
REPORT to create a table that lists the attributes you specified.
QUERY ATTRIBUTE to query a specific point on the plotted well-location map.
BSEARCH to perform complex Boolean retrievals of information from the attribute file of a map.

FIGURES 9 through 16 and TABLE 2 show various ways you can use the generated maps to analyze the data.

FIGURE 9: PLOtting the map on the computer screen and using the QUERY command to obtain a listing of the multiple attributes for a specific well.

FIGURE 10: A structure map generated by SELEcting the well-location by attribute (elevation), GRIDing the elevation, CONTOURING the grid, SMOOTH or SCANing the contour map to make a smoother looking contour map, and PLOtting the map on the screen or PENPLOtting the map for a cartographic output.

FIGURE 11: An isopach map showing the thickness of a formation. This was generated by SELEcting the formation map by attribute (e.g., thickness), GRIDing, CONTOURING, SMOOTHing or SCANing the contour map, and then PLOtting it on the screen or PENPLOtting the map for a cartographic output.

FIGURE 12: (a) A cross section across the isopach generated by using the PROFILE command. (b) A 3-dimensional model of the isopach map using the 3D command.

FIGURE 13: A map showing various possibilities for assigning symbols to the wells using the ASSIGN command. See the MOSS manual for tables.

FIGURES 14 through 15 and TABLE 2: Other available data can be added to the well-location map as attributes. In these examples, net feet of porous sand and average porosity were added to the multiple attributes for map analyses. FIGURE 14 shows an isopleth map of the net feet of porous sand and FIGURE 15 shows an isopleth map of the average porosity. Volume of the reservoir can be calculated as follows: (a) use the MATH command to multiply the net-feet-porosity grid, the average-porosity grid, and (1-.378), where .378 is the percent for connate water saturation; (b) use the TOTAL command to calculate acre-feet. TABLE 2 shows a listing of the volumetrics obtained by this method.

FIGURE 16 shows two gas wells, one with a drainage radius of 3839 feet and the other 6216 feet. The leases are PLOtted and SHADEd. There may be probable drainage by the well with the larger drainage as it drains the leases where there are no wells. To create this type of map:

(a) Use the COMPUTE command to create a new attribute using the initial production (gas or oil) and a drainage formula for the producing formation.

Example:

$$10 ** ((3.7 + (LOG (IP.GAS))) / 2)$$

where IP.GAS is an attribute from the PITOMOSS program.

(b) Use the BUFFER-ATTRIBUTE command to buffer each well by the attribute created in step (a).

(c) PLOT and SHADE the leases. PLOT the landlines.

FIGURE 1. Listing of data for a sample well from a PI data file.

the 1990s, the number of people in the world who are under 15 years of age is expected to increase from 1.1 billion to 1.5 billion (United Nations 1994). The number of people aged 65 years and over is expected to increase from 200 million to 350 million in the same period.

There is a growing awareness of the need to take account of the needs of children and young people in the development of health care services. The World Health Organization (WHO) has produced a series of guidelines for the development of health care services for children and young people (WHO 1994). The guidelines are based on the principle that children and young people should be treated as individuals, rather than as a homogeneous group.

The guidelines are based on the principle that children and young people should be treated as individuals, rather than as a homogeneous group. The guidelines are based on the principle that children and young people should be treated as individuals, rather than as a homogeneous group. the 1990s, the number of people in the world who are under 15 years of age has increased by 1.2 billion, from 1.1 billion in 1980 to 2.3 billion in 1999. The number of children under 15 years of age in the world is projected to increase to 3.1 billion by 2015 (United Nations 1999).

There is a growing awareness of the need to address the needs of children in the world, and the United Nations has developed a number of initiatives to address this. The United Nations Children's Fund (UNICEF) is the United Nations agency responsible for the welfare of children, and has a number of programmes in place to address the needs of children in the world. The United Nations Development Programme (UNDP) is also involved in a number of initiatives to address the needs of children in the world.

The United Nations has also developed a number of initiatives to address the needs of children in the world. The United Nations Children's Fund (UNICEF) is the United Nations agency responsible for the welfare of children, and has a number of programmes in place to address the needs of children in the world. The United Nations Development Programme (UNDP) is also involved in a number of initiatives to address the needs of children in the world.

FIGURE 13. Map showing well locations plotted with a variety of symbols available in MOSS using the ASSIGN command.

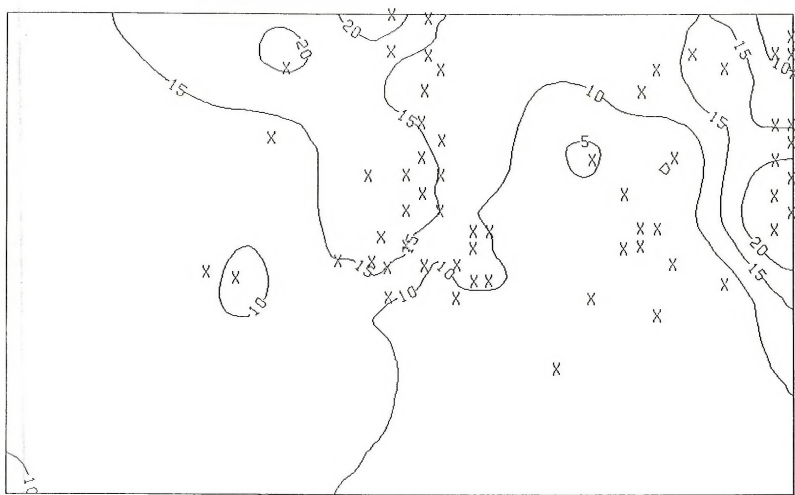

FIGURE 14. Isopleth map showing the net feet of porous sand.

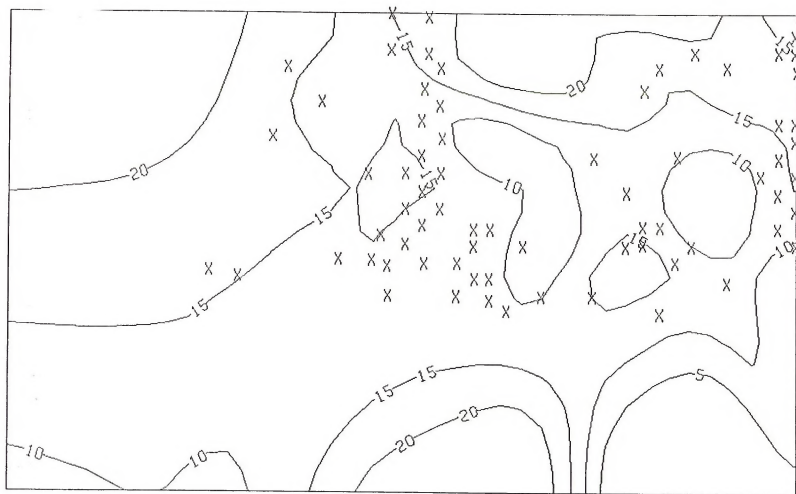

FIGURE 15. Map showing the average porosity.

TABLE 2. Listing of volume of the reservoir, using 37.8 percent for connate water saturation. Volume was calculated by first using the MATH command to multiply the net-feet-porosity grid, the average-porosity grid, and (1-.378) and then using the TOTAL command to calculate the volume of the reservoir.
